Cytotoxic Effects of Britannin on Acute and Chronic Myeloid Leukemia Cells Through Inducing p21-Mediated Apoptotic Cell Death

Hassan MOHAMMADLOU1, Maryam HAMZELOO-MOGHADAM2, Marzieh MOEINIFARD3, Ahmad GHAREHBAGHIAN1,4*

INTRODUCTION

For a long time, herbal medicines have catered to the basic needs of humans to treat various diseases such as cancer. The success of vinca alkaloids, a group of drugs isolated from the periwinkle plant; *Catharanthus roseus* (L.) G. Don, for treating hematologic malignancies -indeed- has begun a new era in terms of cancer treatment strategies.1 Thus far, many compounds provided from natural sources have found their way into the treatment of different human cancers.3 Curcumin,4 trabectedin,5 and resveratrol6 are all-natural compounds that recently enjoyed unprecedented success for treating human cancers. Ergold is another natural compound isolated from *Inula oculus-christi* L., which showed anti-leukemic effects in acute lymphoblastic leukemia (ALL)-derived cell lines. Also, *Artemisia annua* L. (Turk J Pharm Sci 2022;19(3):314-321 DOI: 10.4274/tjps.galenos.2021.88655)

Objectives: Following the success of natural compounds for treating solid tumors, interest in applying such agents for treating hematologic malignancies has been fired up more strikingly. Thus far, anti-leukemic effects of several compounds have been examined in different leukemia cell lines, especially in acute lymphoblastic leukemia. The agent that has recently attracted tremendous attention is Britannin, which is derived from *Inula aucheriana* DC., a plant that grows in Iran (Azerbaijan) and Türkiye. In this study, we evaluated the effects of this compound in myeloid leukemia for the first time.

Materials and Methods: We treated chronic myeloid leukemia (CML)-derived K562 and acute myeloid leukemia (AML)-derived U937 cells with different concentrations of britannin. We used several assays, including trypan blue, 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide, bromodeoxyuridine/5-bromo-2'-deoxyuridine, flow cytometry, and quantitative real-time polymerase chain reaction analysis, to study anti-leukemic effects of the compound.

Results: Our results show that while britannin remarkably reduced the survival of both cell lines in a concentrations-dependent manner, it had cytotoxic effects neither on mouse fibroblast-derived L929 cells nor on normal peripheral mononuclear cells. Moreover, among the tested cell lines, the viability of CML-derived K562 cells was inhibited at higher concentrations of the compound compared with AML-derived U937 cells. We found that britannin induced apoptotic cell death in both cell lines by altering the expression of anti- and pro-apoptotic genes. Britannin also hampered proliferative capacity of the cells in a p21/p27-dependent manner.

Conclusion: Overall, we suggest that based on the lack of toxicity on the normal cells and valuable anti-leukemic activities, britannin could be a promising agent in the treatment strategies of both CML and AML. However, further investigations must more precisely study this compound’s mechanism of action and evaluate its safety profile.

Key words: Acute myeloid leukemia, chronic myeloid leukemia, britannin, cytotoxic effects, apoptosis

extract has been reported to not only to induce caspase-3-dependent apoptosis in ALL cells, but also to increase the sensitivity of the leukemic cells to chemotherapeutic drugs.\textsuperscript{7} \textit{Bryonia aspera} Steven ex Ledeb. extract has also been reported to have anti-proliferative and pro-apoptotic effects in ALL-derived Nalm-6 and REH cells.\textsuperscript{8} During the burgeoning success of these reports and the astonishing roles of natural compounds in treating hematologic malignancies, there is a consensus that natural compounds could probably change the paradigm of treatment in human leukemia. Recently, promising results have been published about the cytotoxic effects of britannin, a sesquiterpene lactone (SL), which is derived from \textit{Inula aucheriana} DC., a plant that grows in Iran (Azerbaijan) and Türkiye.\textsuperscript{9,11}

It has been declared that apart from the anti-inflammatory effects, there is the presence of α-methylene-γ-lactone in sesquiterpene lactones (SLs) that endows their ability to induce cell death in cancer cells.\textsuperscript{12} For example, in breast cancer, Hamzeloo-Moghadam et al.\textsuperscript{13} have reported that low concentrations of britannin reduced the viability of MCF-7 cells through the suppression of cyclin D1 and CDK4 protein. In another study, this compound exerted cytotoxic effects in hepatocarcinoma, breast cancer, and lung cancer\textsuperscript{7} Cui et al.\textsuperscript{14} also suggested that britannin induced apoptotic cell death in liver cancer cells. In the most recent study, Mohammadiou et al.\textsuperscript{15,16} reported anti-leukemic effects of britannin in ALL cells. The authors suggested that this compound induced G1-cell cycle arrest and increased intracellular levels of reactive oxygen species (ROS) in ALL cell lines. Although many studies have been focused on anticancer effects of britannin, as far as we are aware, no study has evaluated the effects of this compound in myeloid leukemia cells and our study examined anti-leukemic effect of britannin in chronic myeloid leukemia (CML)-derived K562 and acute myeloid leukemia (AML)-derived U937 cells for the first time.

MATERIALS AND METHODS

Britannin isolation

\textit{I. aucheriana} was collected and its scientific name was confirmed at the Herbarium of Traditional Medicine and Materia Medica Research Center (TMRC), Shahid Beheshti University of Medical Science (voucher number: TMRC 3173). To obtain britannin, 600 g of \textit{I. aucheriana} dried powder was soaked with \textit{n}-hexane (plant: solvent ratio, 1:10) for three days. After filtration, the same process was repeated with chloroform with the residue of the plant. Seven g of the dried chloroform extract was set to vacuum liquid chromatography (silica gel 40-63 μm; mobile phase: ethyl acetate and methanol); 400 mg of the fraction eluted with EtOAc-MeOH (2:1) was further processed by solid-phase extraction (2.5 × 7.5 cm silica gel 40-63 μm; mobile phase: dichloromethane, ethyl acetate, and methanol) to afford britannin (70 mg).

Cell culture

To evaluate the effect of the britannin on AML and CML derived cell lines, we cultured U937 and K562 cells in RPMI1640 medium containing 10% fetal bovine serum, 50 mg/mL streptomycin, and 30 mg/mL penicillin in a humidified incubator, respectively. We treated the cells with different concentrations of the compound (0-10 μM) for 24 and 48 h. We also cultured L929 cells, a non-cancerous cell line derived from mouse fibroblasts, and peripheral mononuclear cells (PBMCs) as a control to determine the safety of the compound.

Trypan blue assay

After incubating U937 and K562 cells with different concentrations of britannin (0, 3, 5, and 10 μM) for 24 and 48 h, we stained the drug-treated cells with trypan blue dye. After remaining for 2-3 min at room temperature, the number of viable cells was counted manually using a light microscope.

3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay

MTT assay was used to evaluate whether britannin could reduce metabolic activity of the leukemic cells. Drug-treated leukemic cells were exposed to 100 μL MTT solution (0.5 mg/mL) and were incubated for 4 h. After centrifugation and discarding the medium, 100 μL dimethyl sulfoxide was added to each well and, then, absorbance of each sample was measured at 570 nm by an ELISA reader.

Annexin V/PI staining assay

Annexin V-FITC staining was used to assess the effect of britannin on the induction of apoptosis in leukemic cells. Both cell lines were treated with the desired concentrations of the compound, and after 48 h, 5 μL of annexin V-FITC dye was added to each sample. Leukemic cells were incubated in the dark for 15 min and the induction of apoptosis was evaluated using BD FACS Calibur (BD biosciences, SanJose, CA, USA). The Flowjo 7.6 software was used for data analysis.

Gene expression analysis

To study the alterations in gene expression, the first RNA was extracted from drug-treated leukemic cells using Trizol reagent. After evaluating the quality of the extracted RNAs by Nanodrop, cDNA was synthesized by TAKARA kit (Japan). Real-time polymerase chain reaction (RT-PCR) was performed using SYBR green PCR. ABL was the housekeeping gene in this study. The primers used to evaluate the expression of genes are shown in Table 1.

Statistical analysis

One-way ANOVA and post-hoc Tukey multiple comparisons were used for data analysis. All analyses were performed using SPSS software version 22. A p value <0.05 was considered statistically significant.

RESULTS

Effects of britannin on the viability and the metabolic activity of U937 and K562 cells

To evaluate whether britannin could reduce the population of leukemic cells, two myeloid leukemia cell lines, U937 and K562, were treated with increasing concentrations of the

RT-PCR: Real-time polymerase chain reaction

Britannin induced apoptotic cell death in K562 and U937 cells

To determine whether the treatment of cell lines with britannin could induce apoptotic cell death, we treated both cell lines with different concentrations of the compound (0-9 µM) and then binding of annexin-V combined with PI was analyzed by flow cytometry. As presented in Figures 3A and B, we found a significant elevation in the percentage of annexin-V and annexin-V/PI double-positive cells compared to the control group. In agreement with the MTT and trypan blue assay results, U937 cells were more sensitive to britannin than K562 cells. Moreover, to confirm these results, we also evaluated effect of the compound on expression of both anti- and pro-apoptotic genes. The results of the quantitative RT-PCR analysis indicated that while britannin could remarkably increase the expression levels of pro-apoptotic genes, including Bax, Bad, and PUMA, it could reduce the expression of anti-apoptotic genes such as Bcl2, Bcl-xl, and MCL-1 (Figure 4).

DISCUSSION

From the first description of human leukemia until now, efforts were made to find a proper treatment for this type of disease. However, the heterogeneity between different sub-types of leukemia, whether they are categorized as chronic leukemia or acute leukemia, did not lead to the development of a single treatment regimen for both disease. The clinical use of targeted therapies also fail to introduce one specific small-molecule inhibitor to treat both acute and CML. The development of resistance to agents has been a major challenge, and the search for new agents with more potent anti-leukemic effects and lower side effects continues. A stream of efforts for finding new agents with more potent anti-leukemic effects and lower side effects is on the way. Attention has also been attracted to herbal medicines, as many drugs isolated from plants have been shown to be safe and well-tolerated in clinical investigations. In this study, we evaluated the effect of britannin, a compound
Figure 1. The effect of Britannin on the viability and the metabolic activity of K562 and U937 cells. (A) Britannin concentrations of 3, 5, and 10 µM significantly reduced the survival and number of viable cells in both leukemic cell lines. (B) The results of MTT assay revealed that Britannin could hamper the metabolic activity of the cells in a concentrations-dependent manner. (C) Britannin at the concentrations of 3, 5, and 10 µM had toxic effects neither on L929 cells or on PBMCs. Values are given as mean ± SD of three independent experiments.

*p<0.05 represents significant changes from untreated control, MTT: 3-(4,5-Dimethylthiazol-2-y0)-2,5-diphenyltetrazolium bromide, PBMCs: Peripheral mononuclear cells, SD: Standard deviation
isolated from *I. aucheriana*, on two myeloid leukemia cell lines, e.g. K562 and U937, which are derived from CML and patients with AML, respectively.

Interestingly, our results showed that britannin remarkably reduced the number of viable cells, cell growth, and metabolic activity of U937 cells in a concentration-dependent manner. However, for K562 cells, a significant anti-leukemic effect of the compound was obtained at a higher concentration (10 µM). This finding suggested that, compared with U937 cells, CML-derived K562 cells were more resistant to the lower concentrations of britannin. Our results also showed that this single compound at the same concentrations had neither cytotoxic effects on L929 cells nor normal PBMCs.

Note that among the tested cell lines, we found that viability of CML-derived K562 cells was inhibited at higher concentrations of the drug, as compared with AML-derived U937 cells. This difference in cell sensitivity could be due to the excessive activation of PI3K/Akt signaling pathway in K562 cells because of the presence of BCR-ABL. It has been well-established that the PI3K/Akt activity could induce the drug-resistance in CML cells. However, britannin reduced survival of K562 cells at concentrations that had no toxic effects on the normal cells.

Having established anti-leukemic activity of britannin on both leukemic cell lines, we also examined the mechanism through which this compound might induce its effects. Our results showed that britannin reduced the capability of the leukemic cells to replicate DNA. The results of the BrdU assay revealed that in the presence of britannin, there was a significant decrease in the DNA synthesis rate in both K562 and U937 cells, which in turn hampered the ability of the cells to proliferate. Similarly, britannin concentration-dependently reduced the number of viable cells in both cell lines. In agreement with our finding, Zhang et al. also indicated that britannin could reduce proliferation of cancer cells. It has been indicated that britannin interacts with c-Myc and thereby hampers the proliferative activity of PDL-I-positive T-cells in the tumor site, an event that in turn prevents the growth and metastasis of cancer cells. Proliferation of leukemic cells could be regulated via the alterations in the genes controlling the progression of the cell cycle. Thus

![Figure 2. Anti-proliferative effects of britannin on K562 and U937 cells. (A) Treatment of K562 and U937 cells with increasing concentrations of britannin led to a decrease in the DNA synthesis rate of the cells. (B) Britannin significantly increased the expression of p21 and p27 in both cell lines. Values are given as mean ± SD of three independent experiments *p<0.05 represent significant changes from untreated control, SD: Standard deviation](image)
far, several cell-cycle regulatory genes such as p21 and p27 have been identified. Moreover, the results of a previous study indicated that britannin could reduce the expression of cyclin D1 and CDK4, two other cell-cycle regulatory genes in breast cancer cells. In line with these results, we also found that britannin increased expression levels of both p21 and p27 in leukemic cell lines, suggesting that anti-proliferative capacity of britannin in K562 and U937 cells is mediated, at least in part, through altering the expression of the genes controlling the distribution of the cells in the cell cycle. Apart from regulating progression of the cells from G1 phase of the cell cycle to S phase, p21 could also increase expression of pro-apoptotic genes such as Bax in the cells. It has also been declared that elevation in the expression of p21 could increase the sensitivity of cancer cells to apoptosis by increasing the expression of p53-related genes. In another study, Hastak et al. reported that ablation of p21 in prostate cancer cells prevented epigallocatechin-3-gallate, a polyphenolic compound of green tea, induced apoptotic cell death. In agreement with the up-regulation of p21, we found that not only britannin increased the expression of p53-dependent pro-apoptotic genes but also diminished the expression of anti-apoptotic genes such as Bcl2, MCL-1, and BCL-xl. Moreover, this compound significantly increased the population of apoptotic cells in both K562 and U937 cells. Cui et al. also showed that this compound hampered viability of liver cancer cells by elevating the intracellular concentrations of reactive oxygen specious, which eventually induced apoptotic cell death. As the most straightforward interpretation of our results, we suggested that probably britannin reduced survival and proliferative capacity of myeloid leukemia cells via p21-mediated suppression of DNA synthesis and induction of apoptotic cell death.

**CONCLUSION**

Taken together, the results of this study indicated that based on minimal toxicity on the normal cells and valuable anti-leukemic activities, britannin could be introduced in the treatment strategies of leukemia, whether CML or AML. However, further investigations must more precisely investigate the mechanism.
of action of the compound and to evaluate its safety profile in a xenograft model.
