ABSTRACT

*Lepidium sativum* L. is a common herb distributed worldwide, used as a food ingredient and therapeutic agent in traditional medicine for treating health-related disorders. *L. sativum* and its extracts have been described to possess numerous biological activities including antimicrobial, antidiabetic, antioxidant, antidiarrheal, anticancer, and numerous health-promoting effects in *in vivo* and *in vitro* studies. The purpose of this review is to summarize the findings describing important biological functions and therapeutic effects of *L. sativum* in various cell lines and animal models. In this review, the English-language articles were gathered from electronic databases including Web of Science, PubMed and Google Scholar with no time limit applied to any database. The search terms used in this review include, "*Lepidium sativum* L." and/or "chemical composition", "health benefits", "antimicrobial", "antioxidant", "anticancer", "diuretic", "nephro-protection", "antidiarrheal", "anti-diabetic", "anti-asthmatic", "neuroprotection", "metabolic", "bone fracture", and "reproductive performance". Additional and eligible studies were collected from reference lists of appropriate articles. The information presented will be helpful to attract more interest toward medicinal plants by defining and developing novel clinical applications and new drug formulations in the future. Pre-clinical studies showed that *L. sativum* possesses potent health-promoting effects involving various molecular mechanisms. Taken all together, data suggested that identified herbal plants such as *L. sativum*, can be exploited as nutritional and therapeutic agents to combat various ailments. Despite much research in this field, further comprehensive *in vitro/*in vivo studies and clinical trials are needed to identify the mechanisms underlying the biological and therapeutic activities of *L. sativum*.

Key words: Ethnomedicine, medicinal plants, *Lepidium sativum*, nutraceutical, therapeutic agents

INTRODUCTION

Many plants have been considered a principal source of potent therapeutic drugs for centuries. *Lepidium sativum* L., (alias Garden cress) is a fast-growing perennial herb with edible leaves that grows up to 50 cm in height and belongs to the family Brassicaceae (Cruciferae).1-3 It is widely dispersed throughout the world; Africa, Asia, Australasia, Europe, Northern, and Southern America.4-6 The leaves and seed oils are commonly applied in traditional medicine to treat various clinical complications, including asthma, hypertension, hyperglycemia, hepatitis, menstrual problems, sexual debility, arthritis, fracture, diarrhea, vitamin C deficiency, constipation, and migraine.7,8 Additionally, they have been represented with pharmacological properties such as immunity booster, anticancer, antioxidant, laxative, febrifuge, diuretic, and galactogogue activities (Figure 1).9,10 The chemical composition of the *L. sativum* seeds illustrated that they contain high levels of proteins, fatty acids (oleic and linolenic acids), crude fiber (lignans, etc.), essential minerals (potassium, phosphorus, calcium, and iron), phytosterols (sitosterol, campesterol, and avenasterol), carotenoids, alkaloids (lepidine, N, N'-dibenzylioureia, N, N'-dibenzyl urea,
Therapeutic effects of *Lepidium sativum* under various physiological/pathological conditions

(sinapine), hydroxycinnamic acids (sinapic acid), glucosinolates (glucotropaeolin and 2-phenyl ethyl glucosinolates), riboflavin, ascorbic acid, and tocopherols. Toxicological studies state that *L. sativum* seeds are considered practically non-toxic and safe. Nowadays, ethnomedicinal studies gained great attention due to their beneficial roles against various ailments, though proper identification and documentation of medicinal plants seems indispensable. Here, we provided an updated comprehensive overview of the chemical composition of *L. sativum* with focusing on its beneficial impacts, medicinal utility, and underlying mechanisms.

**Chemical composition of *L. sativum***

Various factors (including variety, plant agronomic practices, seed collection stage, and geological conditions) contribute to the differences of the chemical composition of *L. sativum* seeds. *L. sativum* seeds consist of carbohydrates, protein, lipids, and fiber. *L. sativum* seeds also contain mucilaginous substances (cellulose and uronic acid containing polysaccharides). Additionally, the seeds have high protein and lipid contents, minerals as well as vitamins (i.e. vitamins A, C, D, B6, and cobalamin). The presence of numerous components has been reported in *L. sativum* seeds including alkaloids, phenolic compounds, anthraquinones, and cardiac glycosides, flavonoids, tannins, benzoic, dihydrobenzoic, gallic, chlorogenic, 4-hydroxycoumaric, vanillic, and salicylic acids, pyrogallol, catechin, caffeine, isoleucine as well as different imidazole alkaloids e.g. lepideine and semilepideine. Essential (leucine, valine, lysine, phenyl alanine, isoleucine, arginine, histidine, threonine, and methionine) and non-essential (glutamic acid, aspartic acid, glycine, proline, serine, alanine, and tyrosine) amino acids are present in *L. sativum* seeds. Most abundant fatty acid in *L. sativum* seeds is α-linolenic acid (ALA), however, oleic, palmitic, stearic, arachidic, linoleic, lignoceric, behenic, acids β-sitosterol are found in different concentrations. *L. sativum* seed oils comprise high amounts of γ-tocopherol as well as α-tocopherol. Benzyl cyanide and benzyl isothiocyanate are detected as significant volatile components of the seeds. In a recent research, the results of the liquid chromatography-mass spectroscopy (LC-MS) of *L. sativum* extracts demonstrated various secondary metabolites (including kaempferol, apigenin, luteolin, quercetin, and 7-hydroxy-4′,5,6-trimethoxyisoflavone, chlorogenic acid, sinapic acid, ascorbic acid, p-coumaric acid, 6-prenylharingenin, and α-tocopherol) in different concentrations.

**Beneficial effects of *L. sativum***

**Antimicrobial activity***

The growth of antibiotic resistance in bacterial strains and adverse effects of synthetic antibiotics provide a route to exploiting plants with strong medical potential in treating bacterial infections. Many studies have reported that the *L. sativum* extract is effective against bacterial strains and pathogens. It has been proposed that the antibacterial potency of *L. sativum* depends on benzyl isothiocyanate presence. An increasing number of studies confirmed *L. sativum*'s antimicrobial properties (Table 1), however, exact mechanism of action, which elucidates how they could perform such activities has not fully understood. Recently, Al-Otaibi et al. revealed probable therapeutic potential of the methanolic extract of *L. sativum* seeds in *Trypanosoma evansi* (a parasitic protozoan) infected-Swiss albino mice. Their findings showed that the methanolic extract treatment results in restoring the hematology analysis (haemoglobin content, hematocrit, erythrocyte count, leucocyte count, and percentage of lymphocytes) to the pre-infection values. Besides, the study discovered that the intraperitoneal (ip) injection of the extract exerts more efficacy rather than oral administration. In another research it has been shown that the leaf extract of *L. sativum* could inhibit the viability of the protoscolices *Echinococcus granulosus*. Al-Marzoqi et al. examined the antimicrobial potential of the crude alkaloid, phenolic, and terpenoid compounds of *L. sativum* extract. Their findings demonstrated that both Gram-positive and Gram-negative pathogens (*Staphylococcus aureus*, *S. epidermidis*, *S. saprophyticus*, *Klebsiella*, *Serratia*, *Proteus*, *Escherichia coli*, *Pseudomonas*, and *Provedenatia*) were resistant to phenolic compounds, whereas the alkaloid and terpenoid compounds exerted an extensive antimicrobial activity against Gram-positive and Gram-negative bacteria. Over all, they suggested that the hydrophobicity of components of the plant extracts, leads to disruption of bacterial cell membrane lipids and mitochondria that in turn causes microbial death. They also showed that different concentrations of active components of the aforementioned plant demonstrated diverse effects on various pathogenic organisms.

*Figure 1. Therapeutic effects of *Lepidium sativum* under various physiological/pathological conditions*
**Antioxidant activity**

Formation of reactive oxygen species (ROS) is provoked through normal metabolism, however, excessive amounts are detrimental and should be scavenged to avoid any damage.\(^{35}\) Oxidative stress is implicated in the pathogenesis of several chronic ailments such as cancer, cardiovascular disease, and etc.\(^{36}\) Intake of nutraceuticals (rich in antioxidants) from different herbs possibly protect human body against free radicals, thus, alleviate oxidative damage and degenerative diseases.\(^{36}\)

In a study conducted by Aydemir and Becerik, \(^{29}\) L. sativum seed extract exhibited antioxidant activity. In another study, antioxidant activity of L. sativum seed oil (petroleum ether) was evaluated employing free radical (2,2-diphenyl-1-picrylhydrazyl, DPPH) scavenging activity method. The petroleum ether extract exerted antioxidant activity dose-dependently.\(^{29}\) Omer et al.\(^{34}\) reported that the ethyl acetate fractions of the L. sativum seeds had highest antioxidant activity. Another study conducted by Malar et al.\(^{37}\) revealed the substantial antioxidant activity of the ethanolic extract of L. sativum plant parts (shoot, leaf, stem, and seed). Further, it has been shown that the presence of flavonoid and tannin in the methanolic extract of L. sativum leads to the significant antioxidant activity.\(^{22}\)

The cyanobacterial toxins and crude extract provoke oxidative stress response in L. sativum seedlings through lipid peroxidation, elevation of the levels of tocopherol and antioxidant enzymes (including glutathione peroxidase, glutathione S-transferase, and glutathione reductase).\(^{35}\) Furthermore, in a study performed by Kasabe et al.\(^{38}\) it has been elucidated that the seeds of L. sativum possess antioxidant activities due to total phenolic content of the seeds. In a recent study, it was reported that methanolic extract of L. sativum exerted potent radical scavenging activity comparing to the ethanolic extract.\(^{23}\)

**Anticancer activity**

Cancer has remained as the leading cause of death worldwide. Nowadays, applying natural remedies to overcome the side effects of conventional methods in cancer treatment have received growing attention.\(^{39,40}\) L. sativum demonstrated anticancer, antiproliferative and cytotoxic effects through different mechanisms such as induction of apoptosis and necrosis in various cancer cells. An in vitro study carried out on breast cancer cell line (MCF-7), reported the apoptosis induction capability of the aqueous extract of L. sativum seeds. However, high concentrations of the extract resulted in necrosis.\(^{41}\) Recently, El Sayed et al.\(^{42}\) reported the antioxidant and anti-mutagenic effects of L. sativum against in vivo Ehrlich ascites carcinoma (EAC) in Swiss albino mice. Their findings demonstrated anticancer effect of L. sativum in EAC tumor-bearing mice lifespan. Additionally, increased levels of liver enzymes and glutathione peroxidase activity as well as decreased levels of malondialdehyde (MDA) were observed, which in turn indicated the antioxidant properties of the extract. Besides, L. sativum extract decreased chromosomal aberration and DNA fragmentation.\(^{42}\) In another study conducted by Selekh et al.\(^{43}\), L. sativum methanolic extract substantially induced apoptosis in human peripheral lymphocyte cells, colon cancer (DLD-1), and endometrium cancer cell lines (ECC-1) in a dose-dependent pattern, besides, the extract presented significant antioxidant activity. Taken all together, they suggested that high levels of phenolic and flavonoid compounds of the extract may be considered as the underlying mechanism for the anticancer activity of L. sativum.\(^{43}\) The antiproliferative effects of the leaf aqueous extracts of L. sativum were explored on human tongue squamous carcinoma (CAL-27). The aqueous extract inhibited growth of CAL-27 cells concentration-dependently. Apoptosis induction and DNA damage was observed in L. sativum extract-treated cancer cells. ROS generation in the mitochondria of the treated cells seems the cause of apoptosis induction.\(^{44}\) According to a recent study, the hydroalcoholic extract of L. sativum showed cytotoxicity on HeLa cell line.\(^{45}\) Further, Aslani et al.\(^{46}\) evaluated cytotoxic effects of hydro-alcoholic extracts of L. sativum shoots in K562 cell line as a model of CML. MTT assay results depicted that the extract exerted cytotoxic effect on K562 cell line in a dose and time dependently.\(^{46}\)

Effects on urinary system

Diuretic activity

There are different studies suggested that the plant’s diuretic effect may depend on presence of phytochemicals such as flavonoids, saponins, steroids or organic acids.41 In line with this, Patel et al.47 illustrated that the aqueous and methanolic extracts of L. sativum dose-dependently augmented urine secretion in rat models. They suggested that L. sativum extracts’ diuretic activity possibly induced by individual or synergistic effects of flavonoids and steroids, which in turn leads to increased local blood flow and vasodilation or inhibition of water and anions tubular reabsorption.47 In addition to excessive urine production, increased sodium and water excretion contributes to L. sativum’s antihypertensive effect.47 Maghrani et al.48 investigated diuretic and antihypertensive properties of the aqueous extract of L. sativum in normotensive and spontaneously hypertensive rats (SHR). Oral administration of the extract caused substantial drop in blood pressure as well as increase of urinary excretion of sodium, potassium, and chlorides in SHR rats.48

Nephroprotective effect

Numerous evidence elucidates some medications have potential to induce nephrotoxicity and acute renal failure which causes loss of renal functions. Phytochemicals of L. sativum may have antioxidant activity, which, thus, overcome the drug-induced nephrotoxicity.49 In this regard, Yadav et al.49 depicted that the ethanolic extract of L. sativum exerts nephroprotective and curative activity against cisplatin-induced nephrotoxicity in Wistar rats. The administration of the extract markedly declined the levels of urea, creatinine as well as lipid peroxidation and enhanced glutathione (GSH) levels.49 Recently, it has been presented that L. sativum seed aquatic extract could ameliorate oxidative stress induced by dexamethasone in rats. Dexamethasone administration led to the elevation of thiobarbituric acid reactive substances (TBARS), hydrogen peroxide, liver function biomarker levels, and lactate dehydrogenase (LDH) activity. However, enzymatic and non-enzymatic antioxidants, protein content, and alkaline phosphatase (ALP) activity were markedly reduced. The aquatic extract administration in rats received dexamethasone, could alleviate lipid peroxidation, antioxidant status, and biochemical indices, when compared to the dexamethasone-treated group.50 Furthermore, administration of L. sativum powder to the gentamicin-induced nephropathy in diabetic albino rats caused a substantial reduction of the serum levels of glucose, MDA, augmentation of the glutathione transferase (GST), superoxide dismutase (SOD), total antioxidant capacity (TAC), glutathione pyoxidase (GPX), and catalase (CAT) activity as well as serum insulin levels, though exerted nephroprotective effect by enhancing renal damage.51

Effects on digestive tract

Antidiarrheal activity

A few studies reported the antidiarrheal and antispasmodic properties of L. sativum.52 In a study performed in rat model, the administration of extract can inhibit castor oil-induced diarrhea like dicyclomine. Data from the study proposed that dual suppression of muscarinic receptors and Ca2+ channels was responsible for the antidiarrheal/antispasmodic activities of the L. sativum. Moreover, presence of gut relaxant compounds and phytochemicals such as alkaloids, and β-sitosterol, plays an important role in L. sativum antidiarrheal/antispasmodic effect.53 Additionally, they examined antidiarrheal/antispasmodic properties of the crude extract of L. sativum seeds in multiple species (mice, Sprague-Dawley rats, guinea-pigs, and local breed rabbits). They also depicted the antidiarrheal/antispasmodic mechanisms specific to each species as below: 1) in rabbit model: activation of K+ channels and blockade of PDE enzyme, 2) in guinea-pig model: anti-muscarinic and weak Ca2+ antagonist-like pathways and 3) in rat model: a combination of anti-muscarinic, Ca2+ antagonist and PDE-inhibitory-like mechanisms.53

Effect on gut disorders

The aqueous-methanolic extract of L. sativum seeds were reported to be potent contributors to indigestion and constipation (as digestive disorders). Najeeb-Ur-Rehman et al.54 described an in vivo experiment conducted in mouse model displaying the atropine-sensitive pro-kinetic and laxative properties, which were relatively mediated through muscarinic receptors.

Metabolic activity

Findings of a recent study depicted that ethanolic and aqueous extracts of L. sativum significantly exerted hepato-protective, hypolipidemic, hypoglycemic, hypoinsulinemic, anti-obesity, antioxidant, and anti-inflammatory properties in high fat diet-fed rats. Moreover, the hepatic tissues of ethanolic/aqueous extracts-treated rats demonstrated upregulation of the intracellular phosphorylation of common markers of insulin signaling cascade (p-IR/p-AKT/pmTOR/p-p70S6K). Both extracts mitigated lipid peroxidation and restored the amounts of antioxidant enzymes.55 Al-Asmari et al.56 designed a study to assess the hepatoprotective effect of ethanolic extract of L. sativum against carbon tetrachloride (CCl4)-induced toxicity in rat model. Their findings demonstrated that the level of serum alanine transaminase (ALT), ALP, aspartate transaminase (AST), and bilirubin was significantly decreased in ethanolic extract-treated rats. Additionally, histological analysis of liver tissues exhibited mild necrosis and inflammation in extract-treated group in comparison to the CCl4-treated group.56

Similar findings were obtained by Zamzami et al.57 for hepatoprotective effects of L. sativum seeds against CCl4-induced hepatic injury in New Zealand rabbits. The extract-treated rabbits showed significant reduction in serum levels of liver biomarkers (transaminases, γ-GT, and ALP), total bilirubin, cholesterol, triglycerides (TG) and elevated levels of total protein and albumin. Moreover, L. sativum extract reduced oxidative stress in liver tissues. Overall, biochemical analysis as well as histopathological examination revealed that L. sativum extract effectively could reverse the hepatotoxicity of CCl4 in vivo.57 In another study, potential protective and therapeutic effects of L. sativum against aluminum-induced injury of liver and kidney in albino rat were investigated. Data
from this experiment exhibited that administration of the extract led to a marked reduction in levels of serum biomarkers of liver (e.g., AST, ALT, ALP, bilirubin, urea, and creatinine) and kidney functions. It is also significantly augmented total protein and albumin. Besides, rats fed with the extract reversed necrosis of hepatocytes, glomeruli, and renal tubules. It has been suggested that the antioxidant properties of *L. sativum* seeds exerted the aforementioned beneficial effects.58

*L. sativum* seed powder exhibited the potent cardioprotective effect against 5-fluorouracil (FU)-induced cardiotoxicity and oxidative stress in albino rats. *L. sativum* seed powder significantly reduced the inflammatory markers [myocardial IL-1β and myeloperoxidase (MPO) activity], concentration of serum cardiac biomarkers (CK-MB and cTnI), whereas it increased glutathion (GSH) concentration. Moreover, in the *L. sativum*-treated group, the hypertriglyceridemia and hypercholesterolemia factors were returned to the normal status compared to the 5-FU-induced cardiotoxicity group.59 In another research, hypolipidemic activity of *L. sativum* seed extract against triton x-100 and high cholesterol diet (HCD)-induced hyperlipidemia was investigated on rats. Their results showed that the extracts significantly protected against all parameters [total cholesterol (TC), TG, low density lipoprotein cholesterol (LDLc), very low density lipoprotein cholesterol (VLDLc)] of HCD diet-induced hyperlipidemia, thus, may exert anti-hyperlipidemic effect.60 Additionally, Raish et al.61 evaluated hepatoprotective effect of *L. sativum* ethanolic extract in rat model with liver damage induced by D-galactosamine/lipopolysaccharide. Data from their study revealed that the extract significantly down-regulated the pro-inflammatory cytokines (e.g. TNFα and IL-6 mRNA), stress genes (iNOS and HO-1) and up-regulated the IL-10 expression dose-dependently. Furthermore, the extract pretreatment leads to down-regulation of nuclear NF-kB (p65), NF-kB-DNA binding activity, MPO activity, and nitric oxide (NO) level. Additionally, it can down-regulate caspase 3 and up-regulate Bcl-2 protein expression, which overall indicated that *L. sativum* markedly alleviates hepatic damage through reduction of oxidative stress, inflammation, and apoptosis in the liver.51 Administration of *L. sativum* seed ethanolic extract effectively could ameliorate triacylglycerol, LDlc, and TC as well as downregulation of hepatic 3-hydroxy-3-methylglutaryl-coenzyme A reductase and VEGF expression in rat NAFLD model, thus, in turn, impedes obesity, NAFLD, NASH, and fibrosis. Additionally, the extract administration exerted antioxidant activity via increasing GSH, SOD, and CAT activities as well as reduction of MDA and NO levels.62

In another study, Sakran et al.63 isolated 5,6-dimethoxy-2’3’-methylenedioxy-7-C-β-D-gluco-pyranosyl isoflavone (a new isoflavonoid) from *L. sativum* seeds. They showed that this new isoflavonoid have a potential to diminish the hepatotoxicity induced by paracetamol in adult Sprague Dawley male rats. They proposed that hepatoprotective effect depends on enhancing TAC and normalizing level of liver enzymes including GSH, SOD, GPX, CAT, and GST.63

**Antidiabetic activity**

Hyperglycemia (high blood sugar) causes long-term complications in affected people. Untreated hyperglycemia results in renal failure, diabetic cataract, elevated risk of cardiovascular diseases, and excessive generation of free radicals. Numerous lines of evidence suggested ethnomedical plants in order to ameliorate the disease and lessen the side effects of synthetic drugs.64 In line with this, Attia et al.65 demonstrated that *L. sativum* seeds methanolic extract, reduced blood sugar and reversed all biochemical and histological complication of alloxan-induced diabetes in rat model.64 In another study, hypoglycaemic activity of aqueous extract of *L. sativum* seeds was examined in streptozotocin (STZ)-induced diabetic rat model. Their results displayed a significant blood glucose level reduction without any substantial alternation in basal plasma insulin concentration, which supports the concept that its hypoglycaemic activity may occur independent of insulin secretion.65 Another study performed in hypercholesterolemic albino male rats revealed that *L. sativum* seed extract improved lipid profile [decrease in cholesterol, TGs, LDL, and increase in high density lipoprotein cholesterol (HDL)] and markedly diminished blood glucose in comparison to the control group.66 Furthermore, Eddouks and Maghrani67 designed a study to investigate the mechanisms underlying the hypoglycaemic activity of *L. sativum* in STZ-induced diabetic rats. Their results showed that administration of the aqueous extract decreased blood glucose, increased glycosuria, and normalized glycaemia through prevention of renal glucose reabsorption that is independent of any alternations in insulin secretion.67 *L. sativum* seed powder administration in alloxan-induced diabetic male Wistar rats decreased fasting blood glucose levels, glycated haemoglobin (Hb A1C %), TG, lipid profile [TC and lipoprotein fractions (LDLc and VLDLc)]. The extract treatment also elevated the HDLc levels significantly. Additionally, a marked decrease in TBARS levels and increase in GSH and antioxidant enzyme activity was detected in extract treated rats.68 In a more recent study, Ullah et al.69 revealed that light (as great abiotic elicitor) play a critical role in biosynthesis of herbal metabolites. Data from their research illustrated that, callus cultures of *L. sativum* under white light exerted maximum level of phenolic profile, antidiabetic, and antioxidant properties compared to other conditions in vitro.69 It was also marked by L’hadj et al.70 that *L. sativum* flavonoid-rich extract had potential hypoglycemic, hypolipidemic, anti-inflammatory, cytoprotective, and anti-diabetic properties in Wistar rats via enhancing dyslipidemia, insulin sensitivity, inflammation, and pancreas β-cell integrity.70

**Impacts on reproductive health**

Cumulative evidence proposed the capability of herbal medicine in improving reproductive dysfunction or fertility due to their phytochemicals.71 In a recent study in doe rabbit model, *L. sativum* oil increased the level of the reproductive hormones, while improved antioxidant status and reproductive performance (receptivity, conception rate, and litter size).72 Moreover, Kamani et al.72 experimented efficacy of ethanolic extract of *L. sativum* seed on histopathological alternations
of epididymis in STZ-induced diabetic adult male Wistar rats. Their findings exhibited the improved epithelium height as well as reduction of interstitial volume density, fibromuscular thickness, volume density of epithelium through preventing oxidative stress, which, in turn, demonstrated the extract’s protective effect on reproductive system. 

Recently, Asl et al. revealed that co-administration of coenzyme Q10 (CoQ10) and *L. sativum* markedly enhanced the hypothyalamic-pituitary-gonadal axis activity and amplified the reproductive functions in adult male mice. Co-administration of CoQ10 and *L. sativum* resulted in elevation of all features of sexual behaviors and serum testosterone, luteinizing hormone (LH), and follicle-stimulating hormone (FSH) levels as well as sperm viability and motility. Another animal study was performed to examine the impact of aqueous extract of *L. sativum* on fertility criteria in male mice. Findings of this study displayed that extract-treated mice had higher levels of FSH and testosterone. Overall, all the infertility parameters improved in the hyperprolactenemic animals treated with the extract. Histological analysis of the testis in the extract-treated mice exhibited normal status of seminiferous tubule with high number of sperms. Imade and colleagues investigated the effects of *L. sativum* seeds on the male reproductive functions in rabbit bucks. Rabbits fed with *L. sativum* seeds significantly elevated plasma LH concentrations without any significant difference in testosterone levels. Motility and live sperm percentage were significantly decreased in *L. sativum* seed-treated rabbits. Besides, sperm abnormality percent was increased significantly in *L. sativum* seed-treated rabbits dose-dependently. Taken all together, in case of high amount consumption, toxic effects of *L. sativum* seed on sperm quality and testis in rabbit bucks were observed. In another study, *L. sativum* elevated the concentrations of estrogen, progesterone, LH, FSH, and free testosterone hormones in female rabbits. Besides, significant augmentation of sexual receptivity, conception rate, gestation length, litter size, and body weight at birth in extract treated groups were detected. Overall, *L. sativum* elevated reproductive hormone level and performance in vivo.

**Osteoprotective activity**

Osteoporosis is a progressive “skeletal disorder characterized via low bone mass, micro-architectural deterioration of bone tissue leading to increased risk of bone fragility and fracture risk.” In traditional medicine, *L. sativum* seeds have been proposed to have potential in healing bone fractures. In light of this record, recently, the fracture healing potential of the methanolic and aqueous extracts of *L. sativum* seeds in rats was experimented by Dixit et al. Biochemical and radiological analysis revealed that the methanolic extract markedly led to callus formation. It has been reported that ibuprofen exerted toxic effects on the osteocytes in bone tissue, whereas various concentrations of the aqueous extract of *L. sativum* seeds inhibited the effects of ibuprofen in male albino rats. Administration of teriparatide (a recombinant parathyroid hormone utilized as antosteoporotic therapy) and *L. sativum* seeds ameliorated biochemical, histological, and morphometric bone alternations induced by glucocorticoids in male guinea pigs through osteocytes apoptosis reduction as well as osteoclasts elevation. Abdallah et al. examined osteoprotective effect of *L. sativum* extract in an ovariectomized rat model. Their findings demonstrated that the extract improved bone weight, bone formation biomarkers (LDH and osteocalcin) levels, and free radical scavenging activity (through enhancing SOD and GPX activities). Furthermore, oral administration of the extract results in increase of the bone resorption markers [e.g. carboxyterminal telopeptide, type I and, tartrate-resistant acid phosphatase (TRAP)] and regulation of receptor activator of nuclear factor kappa-B ligand/osteprotegerin expression. Taken all together, they suggested that presence of glucosinolates, lignans, coumarins, phenolic acids, and alkaloids leads to the aforementioned antosteoporotic effects synergistically. In another research, the synergistic antosteoporotic activity of *L. sativum* and alendronate in glucocorticoid-induced osteoporosis was evaluated by methylprednisolone injection in adult female rats. Their findings revealed that *L. sativum* alone and/or in combination with alendronate treatments, markedly diminished serum TRAP and improved bone-ALP, phosphorus, calcium, and bone architecture (through increasing trabecular area or bone marrow area percentage in the proximal femoral epiphysis). Further, Juma revealed that *L. sativum* seeds significantly improved fractures healing in New Zealand white rabbits, which documented via direct measurements of callus formation in millimeters at the longitudinal medial and longitudinal lateral and circumferential areas. Administration of *L. sativum* seed powder to the rabbits with bone fractures demonstrated a significant increase in bone markers, e.g. osteopontin and vitamin D, parathormone, and lactoferrin levels as well as reduction in serum levels of osteocalcin, when compared to the untreated group.

**Anti-asthmatic activity**

Bronchial asthma is a chronic inflammatory disease of airways of the lung, characterized by hyper-reactivity of the airways to various stimuli. Its clinical manifestations include paroxysmal dyspnea, wheezing cough, and a sense of thoracic constriction. From ancient times, the efficacy of the natural remedies in healing various diseases including bronchial asthma, hiccup, cough, etc. has been elucidated. Nevertheless, there is lack of scientific studies, which investigated the efficacy of *L. sativum* in bronchial asthma treatment. For that reason, Paranjape and Mehta carried out a clinical trial to assess the efficiency and safety of *L. sativum* in bronchial asthma affected patients. After 4 weeks of treatment with *L. sativum* seed powder, substantial improvement in several parameters of pulmonary functions, clinical symptoms, and severity of asthmatic attacks without any adverse reaction were observed in asthmatic subjects. In another study carried out on guinea pigs, the bronchodilatory effect of the ethanolic extract of *L. sativum* seeds was investigated in histamine and acetylcholine induced acute bronchospasm. Data from their study showed that the extract, markedly protected guinea pigs against bronchospasm in comparison to the ketotifen and atropine sulphate (as reference drugs). Additionally, Rehman et al. indicated that a combination of anticholinergic, Ca antagonist,
and PDE inhibitory pathways were responsible for *L. sativum*’s bronchodilatory activity.

**Neuroprotective effects**
A few studies stated potential neuroprotective activity of *L. sativum*. In this regard, El-Ghazouly et al. assessed neuroprotective effects of *L. sativum* aqueous extract on the cerebellum of adult male albino rats. Methotrexate exerted adverse effects on cerebellum by reducing the number of Purkinje cells with significant reduction of Nissl’s granules. However, in methotrexate and *L. sativum* aqueous extract administrated rats approximately normal histological appearance of Purkinje cells with less vacuolated cytoplasm was observed, which was validated by a substantial rise in the Purkinje cells number, significant diminution in caspase-3 positive cells and in GFAP immunostaining. Moreover, neuropharmacological impact of the alkaloid of *L. sativum* was evaluated in Swiss albino mice and Wistar albino rats. The results of this study elucidated sedative, anxiolytic, myorelaxant, and analgesic effects of *L. sativum* alkaloid through diminished locomotor activity and motor coordination, and increased preference to plus maze open arm. Al-Dbass et al. examined the potential beneficial impact of *L. sativum* seed extract against glutamate excitotoxicity-induced retinal ganglion cell degeneration, which results in severe blindness. The extract enhanced the cell viability in retinal ganglion cells after exposure to the high concentrations of the glutamate. Thus, they deduced that *L. sativum* seed extracts might exert effective anti-excitotoxic and antioxidant activity in various neurological disorders.

**Other medical effects**
Several studies have evaluated various beneficial effects of *L. sativum* extract in animal models. The ethanolic extract of *L. sativum* seeds significantly prohibited carrageenan-induced paw edema and reduced the yeast-induced hyperpyrexia in mice models and exerted anti-inflammatory and antipyretic effects, respectively. The coagulation studies demonstrated elevated levels of fibrinogen and negligible reduction in prothrombin time, which, in turn, validated the coagulant activity of the extract. The ethanolic extract of *L. sativum* seeds exerted significant anti-inflammatory activity in carrageenan-induced paw edema in mice through improving biomarkers of inflammation (serum albumin, C-reactive protein, and plasma fibrinogen) in comparison to the control group. Alkarfy et al. examined drug-herb interactions and proposed that simultaneous consumption of herbs significantly changed the phenytin (an anticonvulsant drug) disposition in a dog model. In a follow-up study, the methanolic extract of *L. sativum* seed exerted genoprotective effect by inhibition of DNA aberrations in somatic and germ cells of mice dose-dependently. They proposed that the flavonoidal content and antioxidant activity may be responsible for this beneficial properties. Another *in vivo* study performed to evaluate the safety of *L. sativum* seeds powder in adult Wistar rats. Administration of *L. sativum* powder considered non-toxic and safe because of insignificant changes in food intake, gain in body weight, relative weight of organs, e.g. liver, lungs, kidney, spleen, brain, adrenals, gonads, and heart, hematological parameters [including: red blood cells (RBC), white blood cells (WBC), hemoglobin, mean corpuscular hemoglobin (MCH), and MCH concentration], macroscopic and microscopic changes in vital organs, in the experimental group in comparison to the control group. In a recent study, for the first time, the effects of the aqueous *L. sativum* seed extract on the immune system and general health were reported in mice model. The results demonstrated that the extract caused a boost in immune system through WBC types, RBC, and platelet counts as well as mean hemoglobin concentration, mean total body weight gains, and weights of the organs. Moreover, addition of *L. sativum* seeds to the diet of rats for the first 3 weeks, resulted in elevated mean body weights and body weight gains. In a study performed by Kaur and Sharma, it has been elucidated that the supplementation of *L. sativum* seeds (for 2 months) moderately increased the haemoglobin (g/dL) levels among anemic adolescent girls possibly because of iron content.

Diwaker et al. investigated the modulatory effect of ALA-rich *L. sativum* seed oil on lipid composition, spleen lymphocyte proliferation and inflammatory mediator production in rat model. Data from their research illustrated that the extract modulates inflammatory mediators (NO, leukotriene B4), consequently alleviates inflammatory responses.

**CONCLUSION**
Various herbs and their extracts have gained substantial interest since they encompass diverse phytochemicals which represents numerous health-promoting activities. Using different parts of *L. sativum*, several pre-clinical studies demonstrated their potential in alleviating different disorders and improving health (e.g. antimicrobial, antioxidant, anticancer, antidiabetic, anti-asthmatic, and many other protective activities). Hence, *L. sativum* has been considered as an attractive alternative over the conventional therapeutics due to their nutritional values, and less or no adverse effects. However, further comprehensive studies are required to define molecular mechanisms underlying certain health-promoting properties and provide more convincing evidence for the efficacy of *L. sativum*.
