ABSTRACT

Objectives: Almond oil marketed for health benefits and cosmetic purposes should be in compliance with the European Pharmacopoeia (EP) criteria. Therefore, in this study, 17 almond oil samples sold in pharmacies, herbal shops, online, and cosmetics stores were analyzed in terms of “almond oil” monograph criteria, which have been mentioned in EP 7.0.

Materials and Methods: In this study, 17 almond oil samples sold in pharmacies, herbal, online, and cosmetics stores were analyzed in terms of “almond oil” monograph criteria, which have been mentioned in EP 7.0. Appearance, acidity value, and peroxide value of each sample were determined and the ingredients were identified by thin layer chromatography. Fatty acids were analyzed by gas chromatographic method using flame ionization detector.

Results: It was determined that two of the 17 samples complied with EP 7.0 criteria.

Conclusion: Almond oil, which is currently marketed according to the manufacturer’s own marketing and quality criteria, is excluded from the Turkish Food Codex Standards. Our research has shown that most of the products do not comply with the EP standards. For this reason, it should be ensured that almond oil is listed in this codex and urgent arrangements should be made for quality control analysis.

Key words: Fatty acids, gas chromatography-mass spectrometry, Prunus dulcis, quality control

INTRODUCTION

Türkiye, with its diversity of plant species, is one of the world’s most important gene sources. The almond is one among the important species in this gene source, and is grown or cultivated across widespread in Türkiye. Almond [Prunus dulcis (Mill.) D.A. Webb, syn. P. amygdalus Batsch, and P. communis (L.)] are divided into two varieties,¹ pomologically, sweet almond (P. dulcis var. dulcis) and bitter almond (P. dulcis var. amara) (P. amygdalus Batsch), where all belong to the family Rosaceae, along with raspberries, peaches, apples, and pears. About of 20 species have been reported to grow in Iran, while there have been more than 30 wild species in the world.²

Almonds, which are typically used as snack foods or found as an ingredient in many products,³⁴ have a considerable economic value with their different usage areas (gastronomy, confectionery etc.).⁵⁻⁹ They are commonly cultivated for their fruits¹⁰ and place number one among the products of tree nuts.¹¹ Due to their high nutritional content and their promising effects on human health with their high levels of monounsaturated fatty acid and polyunsaturated fatty acid content, consumption of and demand for almonds remains high.⁵⁻⁷ The almond fixed oil obtained from almond seeds is used as medicine, pharmaceutical, and cosmetic products to treat dry skin disorders such as psoriasis.¹² Many studies on the biological value and chemical properties of nut proteins and oils have been reported.¹³ In vivo studies have reported that almond seeds and oils possess hepatoprotective, anti-inflammatory, anticancer, and immunestimulant effects. Among tocopherols, phytosterols, and many other health-promoting micronutrients,¹⁴ almond with
its high content of mono-unsaturated fatty acids, can reduce
gastric carbohydrate absorption rate and increase insulin
sensitivity, while also helpful for constipation and restless
bowel syndrome. The importance of almond fruit with rich
oleic, linoleic, and linolenic acid content has increased due to
the positive effects on cholesterol and cardiovascular disease in
human, while the observed blood cholesterol-lowering effects
of nuts were far better than what was predicted according to
their dietary fatty acid profiles.

The almond oil market was valued at $1118 million in 2016 and
is expected to reach up to $2680 million by 2023, while the
growth of almond oil market is driven by the rise in production
of aromatherapy products, increase in preference of customers
toward cosmetic products containing natural ingredients,
rapid urbanization, and growth in applications of almond oil in
pharmaceutical industry.

Differences in the major and minor components of the medicinal
oils significantly affect their nutritional, health-promoting
activities, and their organoleptic properties. Therefore, in this
study, 17 almond oil samples sold in pharmacies, herbal shops,
online, and cosmetics stores were analyzed in terms of the
criteria specified in the “almond oil” monograph in European
Pharmacopoeia (EP) 7.0.

MATERIALS AND METHODS

Materials
Seventeen different brands of almond oils were purchased
from pharmacies, herbal, online, and cosmetics stores in
Ankara, Türkiye between 2017 and 2018. All chemicals used
were of analytical reagent grade. Oksan Co., Ltd. (Ankara,
Türkiye) provided helium, hydrogen, and dried air gases for gas
chromatography (GC) with 99.99% purity. Deionized water was
obtained from a Milli-Q water purification system (Millipore,
Bedford, MA, USA).

GC (7890A GC System, Agilent Technologies Inc, US), a
capillary column Rt-2560 (100 m, 0.25 mm ID, 0.2 µm) (Restek
Corporation Bellefonte, US), vial insert, 250 µL, glass with
polymer feet, vial, screw top, 2 mL, amber and cap, screw, blue,
PTFE/red silicone septa (Agilent Technologies Inc., US) were
used.

Methods
Seventeen brands of almond oils were analyzed according to
the criteria of EP 7.0 (appearance, identification, acid value,
peroxide value, and composition of fatty acids) and the results
were compared with the pharmacopoeia quality of reference
standard almond oil from P. dulcis (63445-250 mL, Sigma
Aldrich, Lot BCBV9057).

Statistical analysis
All the results are given for at least in triplicate and the values
are given as mean ± standard deviation. Calculations made
in the statistical analysis were made using Microsoft Excel
software.

RESULTS

Appearance
All oil samples were placed into glass droppers and their colors
were compared with the pharmacopoeia quality of reference
almond oil (Table 1).

Identification
Thin layer chromatography (TLC) was used to identify the
almond oils. C-18 silica TLC plate (Supelco 10 x 10 cm, 0.2
mm) was used as the stationary phase. An approximately 20 mg
of oil sample, and a reference solution of almond oil complying
with “Almond Oil European Pharmacopoeia” standards were
dissolved in 3 mL of CH2Cl2 (for GC MSSupraSolv®). TLC plate
was first eluted with ether (Sigma Aldrich, Germany) mobile
phase up to 0.5 cm. Then, the plate was then removed from
the tank and immersed in the other tank containing CH2Cl2:
glacial acetic acid (Sigma Aldrich, Germany): Acetone (Sigma
Aldrich, Germany) (2:4:5, by volume) mobile phase, and eluted
8 cm. The plate removed from the tank and dried in air, and
then 100 g L⁻¹ solution of phosphomolybdic acid (Sigma Aldrich,
Germany) in alcohol as revelator was sprayed. TLC plate was
heated at 120°C for 3 min. Then, retention times and stain of
the commercial almond oils were compared with the retention
times and stains of reference almond oil from P. dulcis (Figure
1). A thin layer chromatogram of the samples and reference
almond oil (Figure 1) was also compared with the reference
chromatogram in EP 8.0 (Figure 2).

Acid (Ia) and peroxide (Ip) values
Acid value is expressed as milligrams of KOH (Sigma Aldrich,
Germany) required to neutralize the free acids in 1 g of the
oil. Therefore, about 10 g of each oil sample was dissolved in
50 mL of 96% methanol (Merck, Germany) and peroxide-free
ether (Merck, Germany, Germany) mixture (1:1, by volume),
then titrated with 0.1 M KOH in the presence of phenolphthalein
(Sigma Aldrich, Germany) indicator until the pink remained
stable for at least 15 s acid values of samples were compared
with the value of maximum of 2.0 in a 5.0 g oil sample (Table
1).

The peroxide value is expressed as milliequivalent of active
oxygen, the quantity of peroxide contained in 1000 g of the
substance. So, about 5 grams of oil was placed in a 250 mL
conical flask fitted with a ground-glass stopper. 30 mL of a
mixture of chloroform (Merck, Germany) and glacial acetic
acid (2:3, by volume) was added. After the oil dissolved, 0.5
mL of saturated potassium iodide (Merck, Germany) solution
was added and shaken for exactly 1 min, then 30 mL water was
added. It was titrated with 0.01 M sodium thiosulfate (Sigma
Aldrich, Germany) until the yellow was almost discharged. 5 mL
of starch solution was added and continued the titration, until
the color was discharged. It was carried out with a blank test
under the same conditions. Peroxide values were compared the
value of maximum 15.0 in 5 g oil (Table 1).

Preparation of fatty acid methyl esters (FAMEs) standard
All standard solutions were prepared in an ice bath and stored
at -20°C. 0.1 g of FAME37, C4-24 (Sigma Aldrich, Germany)
reference standard was dissolved in 250 µL of CH₂Cl₂ (400 mg mL⁻¹ FAME37, C4-24), and then, 75 µL of 400 mg mL⁻¹ FAME37, C4-24 was diluted to 1.0 mL with CH₂Cl₂ (30 mg mL⁻¹ FAME37).

**Preparation of FAMEs in almond oils**

Each oil was dried at 100-105°C. The oils (1.0 g for each) were weighed into a 25 mL round-bottomed flask with a ground-glass neck fitted with a reflux condenser and a gas port into the flask. Anhydrous methanol (10 mL) and 60 g L⁻¹ KOH (0.2 mL) in methanol were added. The reflux condenser was attached, passed nitrogen through the mixture at a rate of about 50 mL min⁻¹ shacked, and heated to boiling. When the solution was clear, it was continued heating for a further 5 min and cooled the flask and transferred the contents to a separating funnel. The flask was rinsed with 5 mL of anhydrous chromatographic quality of heptane (99%, Sigma Aldrich, Germany), then, the rinsing was transferred to a separating funnel and stacked. 10 mL of a 200 g L⁻¹ NaCl (Sigma Aldrich, Germany) solution was added and stacked vigorously. It was allowed to form two separate phases and transferred the upper organic layer to a vial containing anhydrous Na₂SO₄ (Sigma Aldrich, Germany), allowed to stand, then filtered.

Analysis of FAMEs with GC-flame ionization detector (FID)
FAME37, C4-24 standard, and fatty acids in almond oil were analyzed by GC equipped with an auto sampler model Agilent 7693, and FID. A capillary column Rt-2560 (100 m, 0.25 mm ID, 0.2 µm), vial insert, 250 µL, glass with polymer feet, vial, screw top, 2 mL, amber and cap, screw, blue, and PTFE/red silicone septa were used as the column and sample vial, respectively. GC oven was programmed to 100°C, held for 4 min, and then increased by 3°C min ramp to 240°C, held for 10 min. The injector and FID detector temperatures were 225°C and 250°C, respectively. Injection volume was 2 µL with a split ratio 200:1. Helium was used as the carrier gas at 1.2 mL min⁻¹, 20 cm s⁻¹ at 175°C. FAMEs in the oil samples were identified from the chromatogram by comparing their retention times with standard FAME37, C4-24, and the number of FAMEs in the oil samples was expressed as a percentage by weight of all FAMEs from the total detected fatty acids (Figures 3, 4). Peak area was used for quantitative analysis of FAMEs, where their content in almond oil samples were listed in Tables 2a and b.

DISCUSSION
EP 7.0 states that the appearance of almond oil should be clear or pale yellow. The appearance, acid values, and peroxide values of almond oil samples are given in Table 1. In the evaluations, it was observed that the samples coded s7, s9, s10, s14, and s17 do not have this appearance and their colors are pale green or dark yellow (Table 1).
Calculation of the acid value in fixed oils is an important quality criterion. It also gives an idea of whether the oil has exceeded its shelf life. The increase in the amount of free fatty acids is an indication that there will be a decrease in the stability of the oil.

*SD: Standard deviation, n= 3, bOut of limit, FAME: Fatty acid methyl ester
against oxidation. This situation is defined as the oil becoming bitter. According to EP 7.0, it has been reported that acid value in the almond oil should be “maximum 2.0 in 5 g oil”. When evaluated in terms of this criterion; acid values of the samples coded s3, s7, s10, and s14 (Iₚ = 3.30 to 9.18) were found to be well above the criteria reported (Table 1).

Peroxide content of the oil samples indicates that the oil has started to oxidize. Peroxidation process occurs due to high temperature and light exposure. Contact with metal surfaces can also cause the oil to oxidize faster. Additionally, oxygen breaks down unsaturated fatty acids, resulting in smaller aldehyde molecules such as malonaldehyde. The lower peroxide values indicate the longer shelf life of the oil. A high peroxide value usually indicates poor processing and poor oil quality. According to EP 7.0, it has been reported that the peroxide values in almond oil should be “maximum 15.0 in 5 g oil”. When the results were investigated, the samples, s2 (Iₚ = 17.30) and s17 (Iₚ = 19.59) were found to have high peroxide values compared to the maximum values (Table 1).

The fatty acids in commercial almond oils were identified by comparing their TLC profiles with that of the reference almond oil from *P. dulcis* under the same conditions (Figure 1). Results of the fatty acids reported in the EP 8.0 (Figure 2) were also used for identification of fatty acids of the samples. TLCs obtained from samples s5, s6, s8, s9, s11, s12, and s13 were similar to the reference almond oil chromatogram and the corresponding pharmacopeia chromatogram as shown in Figure 2. Nevertheless, the general profile of samples s1, s2, s3, s4, s7, s10, s14, s15, and s16 coded expressions are not suitable.

Quality of the oil is related to its contents, types, and number of fatty acids. In the almond oil monograph in EP 7.0, defined as “Amygdalae oleum raffinatum” and its fatty oils were obtained from the ripe seeds of *P. dulcis* var. *dulcis* or *P. dulcis* var. *amara*, or a mixture of both varieties.

According to EP 7.0, fatty acid compositions of refined almond oil and virgin almond oil are given as; palmitic acid (4.0-9.0%), palmitoleic acid (0.8% max), margaric acid (not more than 0.2%), stearic acid (3.0% max), oleic acid (62-86%), linoleic acid (20-30%), linolenic acid (0.4% max), arachidic acid (not more than 0.2%), eicosenoic acid (0.3% max), behenic acid (not more than 0.2%), and erucic acid (0.1% max). Supelco FAME37 mix, C4-24 was used as a standard reference material to detect the fatty acids in almond oil with GC-FID.

Fatty acids are defined as the organic compounds formed by a hydrocarbonated chain and a carboxylic acid group, which are normally bound with glycerol-forming acylglycerides (mono-, di- or triglycerides). While α-linolenic acid and linoleic acids are the essential fatty acids, which the human body cannot produce, the unsaturated fatty acids in almond oil (50-81% oleic and 6-37% linoleic acid) become more desirable for the physicochemical and nutritional properties and its significant role in human diet. Their fatty acid profiles depend on the oil’s variety and origin, which affects their stability against rancidity during transport, storage, and directly affecting their products and influencing their price. The oil content and composition of almond seed and the fatty acids are usually referred to as quality characteristic of almond conditions, while the oleic/linoleic acid ratio and tocopherol concentration are used as quality indicators, while the oleic/linoleic acid ratio is significant in determining the quality of the kernel due to its preventive effect on lipid oxidation. When fatty acid contents of the almond oil samples analyzed are evaluated according to the EP 8.0, it is seen that oleic acid (C₁₈:1) amounts of samples with s1, s2, s4, s5, s6, s8, and s9 codes are lower than the reference value and linoleic acid (C₁₈:2) amounts are higher than the reference value (Table 3). This difference may also be due to production of gums, as well as possibility of oxidation of oleic acid (C₁₈:1) to linoleic acid (C₁₈:2).

acid (C_{n\text{H}_{2n+2}O}) depending on the production methods (refined, infiltration, cold press etc.), storage conditions (heat, light, etc.), antioxidant addition and amount. However, the samples with s7, s10, s11, and s12 codes were found to meet the criteria required by the EP 7.0.\textsuperscript{22} When all the results are evaluated; among the 17 almond oil samples sold in the pharmacy, only 2 (s11 and s12) of them were found to meet the EP 7.0\textsuperscript{22} criteria for quality (Table 4).

CONCLUSION

Many vegetable oils are sold with health-promoting claims or statements that they are beneficial against diseases, while almond oils are one of them, as they are sold in “natural”, “organic products”, “local products” shops, cosmetics store chains, and pharmacies. Almond oil, which is marketed for health benefits and cosmetics, must meet the EP criteria. A pharmacopeia’s core mission is to protect public health by creating and making available public standards to help ensure the quality of products, while the user or procurer can make an independent judgment regarding quality, thus safeguarding the health of the public. To establish the necessary quality criteria and show no harm to the user, the almond oil (if for human use) needs to be encouraged to be pharmacopeia compliance. Additionally, currently, almond oil is excluded from the Turkish Food Codex Standards. For this reason, it should be ensured that almond oil is listed in this codex and urgent arrangements should be made for quality control analysis.
